

WASHINGTON MOURNING DOVE BANDING STUDY

Mikal Moore, State Waterfowl Specialist

Dana Base, Associate Wildlife Biologist, Colville District

Ron Friesz, State Waterfowl Specialist (retired)

Don Kraege, Waterfowl Section Manager

ABSTRACT: Harvest rates and population trends of Washington's mourning doves (*Zenaida macroura*) are poorly understood. Historical call count routes are being replaced with a nation-wide band recovery survey. WDFW biologists trapped and banded 3,981 mourning doves from 2003-2005 and 2007. Hatch year birds comprised 78% of all doves banded. Band returns ($n = 205$) show that the majority of doves are harvested locally (89%). The direct harvest rate is estimated at 2.1%; overall harvest rate is approximately 2.9%.

TRAPPING AND BANDING

Biologists used Kniffin modified funnel traps pre-baited with wheat, millet, or sunflower seed.

Doves were banded with standard USFWS bands or double-banded with \$100 reward bands or plain gold bands. Reward bands allow researchers to determine the band reporting rate, currently estimated at 58%.

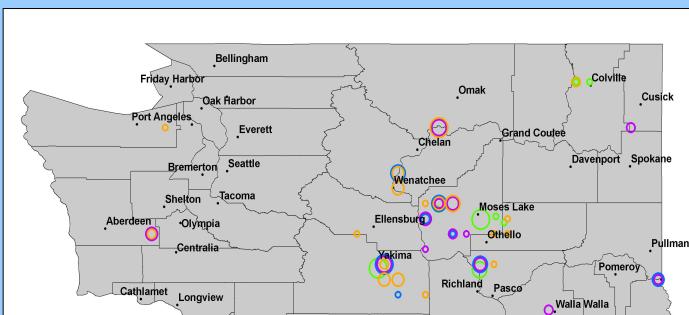

After Hatch Year

Biologists used wing character to determine age. Hatch year birds comprised 78% of doves trapped.

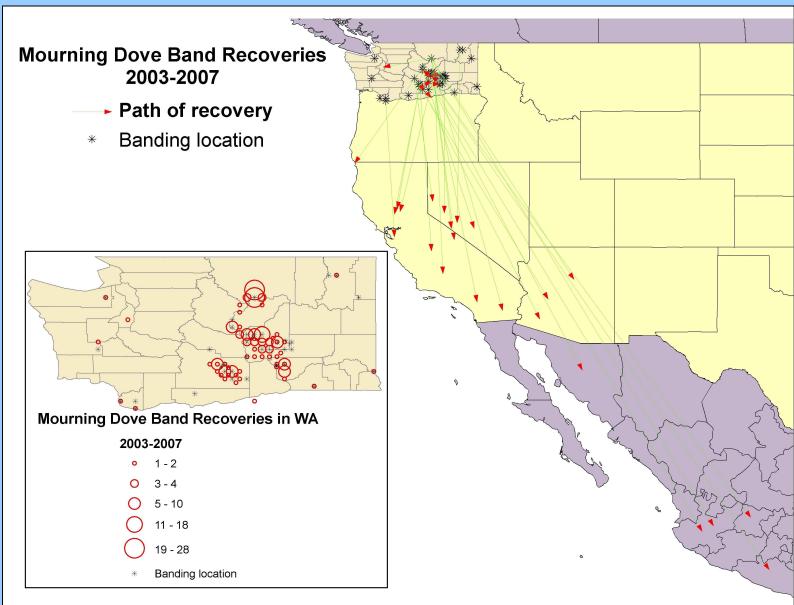

Hatch Year

Dove banding effort was concentrated in central Washington and the Columbia Basin.

BAND RECOVERY

The majority of mourning doves were harvested in Washington (89%). A few made it all the way to Mexico!

YEAR	MODO TRAPPED	BANDS RECOV.	HARVEST RATE	DIRECT HARVEST
2003	919	74	4.5%	2.8%
2004	1,143	67	3.3%	2.2%
2005	1,256	47	2.1%	1.8%
2007	663	17	1.4%	1.4%
TOTAL	3,981	205	2.9%	2.1%

Harvest rates are determined by multiplying the recovery rate by the reporting rate (58%). The sample size for adults was too small to determine age-specific harvest rates.
