July 2020

## Acknowledgments

The Tucannon River Spring Chinook Salmon Hatchery Evaluation Program is the result of efforts by many individuals within the Washington Department of Fish and Wildlife (WDFW) and from other agencies.

We would like to express our gratitude to Lyons Ferry Hatchery Complex Hatchery Specialists Steve Jones, Derek Gloyn, Dan Pounds, and Doug Maxey for their cooperation with hatchery sampling, providing information regarding hatchery operations and hatchery records, and their input on evaluation and research activities. We also thank all additional hatchery personnel who provide the day-to-day care of the spring Chinook and for their assistance with hatchery spawning, sampling, and record keeping.

We thank Andrew Claiborne for providing scale ages and Kelly Britt for providing information on fish health during the year. Special thanks go to David Bramwell for help formatting this report.

We thank the staff of the Snake River Lab; in particular, Joe Bumgarner, Jenna Fortier, Sarah Golden, Todd Miller, Afton Oakerman, Lance Ross and seasonal workers Carson Allessio, Justin Byers, Ali Darnell, Conner Girardin, Brandon Hegsted, Ashish Katru, Rachel Rillera, Chris Rose, and Tyson Schilling who helped collect the information presented in this report.

We thank Joe Bumgarner, Alf Haukenes, Rod Engle, and Laurie Peterson for reviewing the draft report.

The United States Fish and Wildlife Service through the Lower Snake River Compensation Plan Office funds the supplementation program. A grant through the Bonneville Power Administration provided funding for a portion of the hatchery program PIT tags.

Lyons Ferry Hatchery (LFH) and Tucannon Fish Hatchery (TFH) were built/modified under the Lower Snake River Fish and Wildlife Compensation Plan. One objective of the Plan is to compensate for the estimated annual loss of 1,152 Tucannon River spring Chinook caused by hydroelectric projects on the Snake River. This report summarizes activities of the Washington Department of Fish and Wildlife Lower Snake River Hatchery Evaluation Program for Tucannon River spring Chinook for the period May 2019 to April 2020.

A total of 183 salmon were captured in the TFH trap in 2019 (37 natural adults, 2 natural jacks, 115 hatchery adults, and 29 hatchery jacks). Of these, 149 adults ( 36 natural, 113 hatchery) were collected for broodstock, one adipose clipped stray was killed outright, two males were passed upstream (1 natural, 1 hatchery), and 31 jacks (2 natural, 29 hatchery) were held at LFH for outplanting. During 2019, 64 (43.0\%) salmon collected for broodstock died prior to spawning.

Spawning of supplementation fish occurred once a week between 3 September and 24 September, with peak eggtake occurring on 10 September. A total of 126,102 eggs were collected from 7 natural and 38 hatchery-origin female Chinook. Egg mortality to eye-up was $5.7 \%$ (7,213 eggs) which left 118,889 live eggs. An additional $0.6 \%$ (730) loss of sac-fry left 118,159 BY 2019 fish for production.

Weekly spawning ground surveys were conducted from 26 August and were completed by 9 October 2019. A total of 11 redds and 3 carcasses (1 natural, 2 hatchery) were found. Three redds ( $27 \%$ of the total) were counted above the adult trap. Based on redd counts, carcasses recovered, and broodstock collection, the estimated return to the river for 2019 was 203 spring Chinook (43 natural adults, 2 natural jacks and 129 hatchery-origin adults, 29 hatchery jacks).

The 2018 BY smolts were direct stream released on 23-24 March just below Beaver/Watson Bridge (rkm 61.9) as the road to the acclimation pond was washed out due to flooding. An estimated 192,521 BY18 smolts were released.

Evaluation staff operated a downstream migrant trap to provide juvenile outmigration estimates. During the 2018/2019 emigration, we estimated that 17,972 (13,302-25,871 95\% C.I.) natural spring Chinook (BY 2017) smolts emigrated from the Tucannon River.

Smolt-to-adult return rates (SAR) for natural origin salmon are almost eight times higher on average (based on geometric means) than hatchery origin salmon. However, hatchery salmon survive three times greater than natural salmon from parent to adult progeny over the length of the project.

## Introduction

## Program Objectives

Legislation under the Water Resources Act of 1976 authorized the establishment of the Lower Snake River Compensation Plan (LSRCP) to help mitigate for the losses of salmon and steelhead runs due to construction and operation of the Snake River dams and authorized hatchery construction and production in Washington, Idaho, and Oregon as a mitigation tool (USACE 1975). In Washington, Lyons Ferry Hatchery (LFH) was constructed and Tucannon Fish Hatchery (TFH) was modified. Under the original mitigation negotiations, local fish and wildlife agencies determined through a series of conversion rates of McNary Dam counts that 2,400 spring Chinook ( $2 \%$ of passage at McNary Dam) annually escaped into the Tucannon River. The agencies also estimated a $48 \%$ cumulative loss rate to juvenile downstream migrants passing through the four lower Snake River dams. As such, $1,152^{1}$ lost adult Tucannon River origin spring Chinook needed to be compensated for above the project area, with the expectation that the other 1,248 (52\%) would continue to come from natural production. An additional 4,608 were originally assumed to have been harvested in downriver fisheries or in the ocean, and was an additional objective of the plan. The agencies also determined through other survival studies at the time that a smolt-to-adult survival rate (SAR) to the project area of $0.87 \%$ was a reasonable expectation for spring and summer Chinook salmon. Based on an assumed $0.87 \%$ above project area SAR and the 1,152 above project area mitigation goal it was determined that 132,000 smolts needed to be released annually. In 1984, Washington Department of Fish and Wildlife ${ }^{2}$ (WDFW) began to evaluate the success of these two hatcheries in meeting the mitigation goal, and identifying factors that would improve performance of the hatchery fish.

In an attempt to increase adult returns and come closer to achieving the LSRCP mitigation goal, the co-managers agreed to increase the conventional supplementation program goal to 225,000 yearling smolts annually beginning with the 2006 brood year. Size at release was increased to 38 g fish [12 fish/lb (fpp)] beginning with the 2011 brood year. In theory, both actions should have increased adult hatchery salmon returns back to the river, however, it does not appear that these actions will produce enough adult returns to reach the LSRCP adult mitigation goal $(1,152)$.

Because of this, WDFW, along with the co-managers, have initiated an additional hatchery spring Chinook program in SE Washington. A program using Carson stock spring Chinook salmon has been implemented in the Touchet River, with eyed eggs shipped to LFH from the

[^0]2018 and 2019 brood years with the first smolt releases occurring in 2020. Moving forward, adult returns from the Tucannon and Touchet programs will be used to measure contribution towards the LSRCP spring Chinook mitigation goal $(1,152)$ for Washington.

This report summarizes work performed by the WDFW Tucannon Spring Chinook Evaluation Program from May 2019 through April 2020.

## ESA Permits

The Tucannon River spring Chinook population was originally listed as "endangered" under the Endangered Species Act (ESA) on April 22, 1992 (FR 57 No. 78: 14653). The listing status was changed to "threatened" in 1995 (April 17, 1995; FR 60 No. 73: 19342). The listing was reviewed again in 1999 (FR 64 (57): 14517-14528) with the population remaining listed as "threatened" as part of the Snake River Spring/Summer Chinook Salmon evolutionary significant unit (ESU). The WDFW was originally issued a Section 10 Permit (\#848 broodstock collection and monitoring) which expired in March 1998. Permits \#1126 and \#1129 were issued in 1998 to allow continued take for this program, but those permits have since expired. A Hatchery and Genetic Management Plan (HGMP) was originally submitted as the application for a new Section 4 (d) Permit for this program in 2005. An updated HGMP requesting ESA Section 10 permit coverage was submitted in 2011, and was approved in 2016 (Permit \#18024). This annual report summarizes all work performed by WDFW's LSRCP Tucannon Spring Chinook Salmon Evaluation Program during 2019. Numbers of direct and indirect takes of listed Snake River spring Chinook (Tucannon River stock) for the 2019 calendar year are presented in Appendix A (Tables 1-2), along with information required for the NEOR/SEWA Biological Opinion reporting.

## Facility Descriptions

Lyons Ferry Hatchery is located on the Snake River (rkm 90) at its confluence with the Palouse River and has eight deep wells that produce nearly constant $11^{\circ} \mathrm{C}$ water (Figure 1). It is used for adult broodstock holding and spawning, and early life incubation and rearing. Tucannon Fish Hatchery, located at rkm 59 on the Tucannon River, has an adult collection trap on site (Figure 1). Due to a leak in the pipeline at LFH, adults collected during 2019 were held at TFH until the pipe could be fixed. Juveniles from the 2018 BY were transferred to Dworshak National Fish Hatchery (NFH) in Idaho during May and reared in two $85 \mathrm{~m}^{3}$ burrow ponds (3,000 $\mathrm{ft}^{3}$ ) with an average flow of 3,331 lpm ( 880 gpm ). The BY18 fish were transferred back to LFH in August and placed into one of the $18,222 \mathrm{~m}^{3}\left(643,500 \mathrm{ft}^{3}\right)$ lakes with a flow of $13,249-22,713 \mathrm{lpm}$ (3,500-6,000 gpm) for final rearing before release. Curl Lake Acclimation Pond was not used during 2020 because a flood in early February 2020 washed away the road leading up to it.

## Tucannon River Watershed Characteristics

The Tucannon River empties into the Snake River between Little Goose and Lower Monumental Dams approximately 622 rkm from the mouth of the Columbia River (Figure 1). Stream elevation rises from 150 m at the mouth to $1,640 \mathrm{~m}$ at the headwaters (Bugert et al. 1990). Total watershed area is approximately $1,295 \mathrm{~km}^{2}$. Local habitat problems related to logging, road
building, recreation, and agriculture/livestock grazing have limited the production potential of spring Chinook in the Tucannon River. Land use in the Tucannon watershed is approximately $36 \%$ grazed rangeland, $33 \%$ dry cropland, $23 \%$ forest, $6 \%$ WDFW, and $2 \%$ other use (Tucannon Subbasin Summary 2001). Five unique strata have been distinguished by predominant land use, habitat, and landmarks (Figure 1; Table 1) and are referenced throughout this report.

Figure 1. Location of the Tucannon River, and Lyons Ferry and Tucannon Hatcheries within the Snake River basin.

Table 1. Description of five strata within the Tucannon River.

| Strata | Land Ownership/Usage | Spring Chinook Habitat ${ }^{\mathbf{a}}$ | River <br> Kilometer $^{\mathbf{b}}$ |
| :---: | :---: | :---: | :---: |
| Lower | Private/Agriculture \& Ranching | Not-Usable (temperature limited) | $0.0-20.1$ |
| Marengo | Private/Agriculture \& Ranching | Marginal (temperature limited) | $20.1-39.9$ |
| Hartsock | Private/Agriculture \& Ranching | Fair to Good | $39.9-55.5$ |
| HMA | State \& Federal/Recreational | Good to Excellent | $55.5-74.5$ |
| Wilderness | Federal/Recreational | Excellent | $74.5-86.3$ |

${ }^{a}$ Strata were based on water temperature, habitat, and landowner use.
${ }^{\text {b }}$ Rkm descriptions: 0.0-mouth at the Snake River; 20.1-Territorial Rd.; 39.9-Marengo Br.; 55.5-HMA Boundary Fence; 74.5-Panjab Br.; 86.3-Rucherts Camp.

## Adult Salmon Evaluation

## Broodstock Trapping

The allowed collection goal for broodstock is 170 adult salmon, depending upon size and fecundity, collected from throughout the duration of the run to meet the smolt production/release goal of 225,000. The proportion of natural origin fish incorporated into the broodstock is based on the estimated run size and the Tucannon Spring Chinook Salmon HGMP sliding scale. Additional jack salmon may be collected up to their proportion of the run with an upper limit of $10 \%$ used in broodstock, if needed. Returning Tucannon hatchery salmon were identified by coded-wire tag (CWT) in the snout, with no adipose fin clips. All adipose clipped fish captured at the trap are killed outright as strays.

The TFH adult trap began operation in February (for steelhead) with the first spring Chinook captured on 24 May (Appendix B). State and Tribal Fisheries Managers decided to collect all Tucannon River returns that would not be used for broodstock and hold them for outplanting back into the river closer to the commencement of spawning. These measures were taken to reduce potential in-river pre-spawn mortality that has been observed in preceding years.

During 2019, initially all fish captured were held at TFH until work to fix the water pipeline at LFH was completed. Broodstock held at TFH were transferred to LFH in early August. Due to high pre-spawn mortality observed at both TFH and LFH during 2019, all adult fish captured and held were included in the broodstock.

The trap was operated through 30 September. A total of 183 fish entered the trap ( 37 natural adults, 2 natural jacks, 115 hatchery adults, and 29 hatchery jacks) and 149 adults ( 36 natural, 113 hatchery) were collected for broodstock (Table 2, Appendix B). One adipose clipped stray was killed outright, two males (1 natural, 1 hatchery) were passed upstream, and 31 jacks (2 natural, 29 hatchery) were held for outplanting (Table 2, Appendix B). Adults collected for broodstock were injected with tulathromycin (Draxxin ${ }^{3}$ ) at $2.5 \mathrm{mg} / \mathrm{kg}$ but fish held for adult outplants were not injected per WDFW Fish Health regulations. Antibiotic injections for broodstock were repeated 30 days prior to spawning. Broodstock and fish held for outplanting received formalin drip treatments during holding at 167 ppm every other day to control fungus.

[^1]Table 2. Numbers of spring Chinook salmon captured at the TFH trap, trap mortalities, strays or jacks killed outright, fish collected for broodstock, and passed upstream or held for adult outplanting for natural spawning from 1986-2019.

${ }^{\text {a }}$ Fish identified as strays at the adult trap are killed outright. Some hatchery jacks were killed outright in 2016.
${ }^{\mathrm{b}}$ Two males (one natural, one hatchery) captured were transported back downstream to spawn in the river.
${ }^{\text {c }}$ Three hatchery males that were captured were transported back downstream to spawn in the river.
${ }^{\mathrm{d}}$ Ninety-four natural origin fish were collected for broodstock; however, eight natural origin females were returned to the river for natural spawning leaving a total of 86 natural origin fish collected for broodstock.
${ }^{e}$ None of the fish held for adult outplanting in 2017 were outplanted. All of the fish held for adult outplanting were $<61 \mathrm{~cm}$ in fork length (jack size) and were either used to supplement broodstock (natural jacks) or were killed outright.

## Adult Weir/Trap Evaluations

Radio telemetry studies conducted on Tucannon River spring Chinook showed that some spring Chinook were unwilling to enter the TFH fish ladder/trap, leading to high redd densities immediately below the adult trap (Bumgarner et al. 2000, Gallinat et al. 2001, Gallinat et al. 2002). During 2015, 2016, 2018, and 2019, evaluation staff monitored the movement, conversion, and migration delay of returning PIT tagged spring Chinook salmon at the TFH weir/trap (Bumgarner and Engle 2019). A series of temporary and permanent PIT tag antennas that were placed above and below the intake dam, in the fish ladder, and in the adult trap (2019 only) were used for this evaluation. Based on the data obtained over the four years, 96-100\% of the PIT tagged spring Chinook salmon detected below the intake dam enter the fish ladder (Figure 2). In three of the four years, about 65\% were eventually captured (Figure 2). Based on detections above the trap (fish intentionally passed upstream after capture or fish that jumped over the dam), it was estimated that 10-35\% of the fish that were in the weir/trap area remained below the trap (Figure 2). With the installed adult trap antenna in 2019, it was estimated that $41 \%$ of the spring Chinook salmon that entered the adult trap were able to escape, with some eventually recaptured days or weeks later. Based on the 2019 results, and a similar escapement rate of bull trout, the trap fyke opening is being modified prior to the 2020 return. Evaluation staff will continue to monitor the return in 2020 to determine if the new trap fyke opening is effective in retaining salmonids.

Figure 2. Tucannon River spring Chinook salmon passage (conversion) through the Tucannon adult weir/trap, 2015, 2016, 2018, and 2019 (From Bumgarner and Engle 2019).

## Broodstock Mortality

Sixty-four (43.0\%) of the 149 salmon collected for broodstock died prior to spawning in 2019 (Table 3). This rate was higher than recent years due to holding fish at TFH while LFH was undergoing water supply repairs. Mortalities during holding occurred at both TFH and LFH. Cause of death in some fish appeared to be from Bacterial Kidney Disease (see Broodstock BKD Screening and Virology Testing section below). High pre-spawn mortality was experienced when fish were held at TFH in the past (1986-1991), likely due to higher water temperatures (Table 3) and is suspected again as a factor during 2019.

Table 3. Numbers of pre-spawning mortalities and percent of fish collected for broodstock at TFH and held at TFH (1985-1991 and 2019) or LFH (1992-2018).

## Broodstock Spawning

Spawning at LFH was conducted once a week from 3 September to 24 September, with peak eggtake occurring on 10 September. During the spawning process, the eggs of two females were split in half and fertilized by two males following a $2 \times 2$ factorial spawning matrix approach. Factorial mating can have substantial advantages in increasing the genetically effective number of breeders (Busack and Knudsen 2007). The priority order of crosses was Natural x Hatchery, Natural x Natural, and Hatchery x Hatchery, depending upon availability and origin of ripe fish on a weekly basis.

A total of 126,102 eggs were collected from 45 spawned females (Table 4). Eggs were initially disinfected and water hardened for one hour in an iodophor (buffered iodine) solution (100 ppm). The eggs were incubated in vertical tray incubators. Fungus on the incubating eggs was controlled with formalin applied every-other day at $1,667 \mathrm{ppm}$ for 15 minutes. Mortality to eyeup was $5.7 \%$, which left 118,889 live eggs. An additional $0.6 \%$ (730) loss of eggs and sac-fry left 118,159 fish for production.

Table 4. Number of fish spawned or killed outright (K.O.), estimated egg collection, and egg mortality of natural and hatchery origin Tucannon River spring Chinook salmon at LFH in 2019. (Numbers in parentheses were live spawned).

## Broodstock BKD Screening and Virology Testing

Broodstock females were screened for Bacterial Kidney Disease (BKD), caused by the bacterium Renibacterium salmoninarum, using Enzyme Linked Immunosorbent Assay (ELISA). Eighteen percent of the spawned females had high values in 2019 (Table 5). This is higher than values from 2018, but lower than values from 2017, which were believed to be directly related to the decision to suspend antibiotic injections during that year (Figure 3). Eggs and progeny from high BKD ELISA broodstock were segregated for rearing from the rest of the broodstock. Six pre-spawn broodstock mortalities were sampled by the Fish Health Specialist and tissue samples for histopathology were examined at the Washington Animal Disease Diagnostic Lab in Pullman, WA. The results found that the biggest contributor to the high pre-spawn mortality during 2019 was BKD. The Fish Health Specialist will consider switching from tulathromycin injections back to erythromycin injections in 2020 since it seemed to be more effective against BKD.

Spawned females were also examined for viruses and sampling showed no evidence of virus in the samples tested.

Table 5. Enzyme Linked Immunosorbent Assay (ELISA) values for hatchery spawned Tucannon River spring Chinook females, 2019.

| ELISA Value | ELISA O.D. | Number of <br> Females | Percent (\%) |
| :--- | :---: | :---: | :---: |
| Below Low | $<0.099$ | 32 | 71.1 |
| Low | $0.099-0.198$ | 2 | 4.4 |
| Moderate | $0.199-0.450$ | 3 | 6.7 |
| High | $>0.450$ | 8 | 17.8 |
| Total |  | $\mathbf{4 5}$ | $\mathbf{1 0 0 . 0}$ |

Figure 3. Historical Below Low and Low, and Moderate and High ELISA values for Tucannon River spring Chinook salmon female broodstock for the 1998 to 2019 return years.

## Outplanting

After discussions with the Tribal co-managers, it was decided to collect all returning fish not collected for broodstock or killed outright (hatchery strays) and hold them at TFH while the pipeline repairs for LFH were completed. Adults were to be outplanted back into the river during late August near the on-set of spawning. This joint decision was made due to the expected low run size and the high pre-spawn mortality rate of adult spring Chinook salmon that has been documented in the Tucannon River in recent years (Gallinat and Ross 2014; Gallinat and Ross 2015; Snake River Lab 2015).

Fish collected for adult outplanting were given a right opercle punch. These fish were treated with formalin to control fungus growth, but were not injected with antibiotics. However, due to the high pre-spawn mortality levels observed in 2019 at TFH and LFH, all adult fish that were initially held for outplanting were added to the collected broodstock. Of the remaining 31 jacks that were held for outplanting, 10 (32\%) of the jacks (1 natural origin, 9 hatchery origin) were pre-spawn mortalities. Live adult fish were observed above the adult trap during pre-spawn mortality surveys. Therefore, the remaining 21 jacks (1 natural origin, 20 hatchery origin) were outplanted at three different sites on 3 September in order to ensure that males were available for any females that had bypassed the adult trap (Table 6).

Fish that were passed upstream after 2 September were given a left opercle punch. A jack (likely outplanted) was observed paired with a female near Cow Camp Bridge (rkm 72.9), however none of the outplanted jacks were recovered during spawning ground surveys.

Table 6. The number of Tucannon River spring Chinook salmon outplanted in the Tucannon River by release location during 2019.

| Date | Release <br> Location | Rkm | Jacks |
| :---: | :--- | :---: | :---: |
| 9/03/19 | Cow Camp Bridge | 72.9 | 7 |
| 9/03/19 | Camp Wooten Bridge | 68.1 | 7 |
| 9/03/19 | Curl Lake Intake | 66.1 | 7 |
| Totals |  |  | $\mathbf{2 1}$ |

## Natural Spawning

Pre-spawn mortality surveys were conducted from 26 June to 23 August during 2019, after which regular weekly spawning ground surveys commenced. Although fish were not passed above the adult trap prior to 3 September, pre-spawn mortality surveys were still conducted upstream of the trap as we know some fish are able to bypass the trap each year. The pre-spawn mortality surveys covered from Panjab Bridge (rkm 74.5) to Bridge 10 (rkm 43.3) and totaled 168 river kilometers. No carcasses were recovered during pre-spawn mortality walks.

Weekly spawning ground surveys were conducted from 26 August to 9 October 2019 and a total of 234 river kilometers were surveyed. Eleven redds were counted and one natural and two hatchery origin carcasses were recovered (Table 7). Three redds ( $27 \%$ of total) were found above the adult trap, however, no carcasses were recovered. Three carcasses (two hatcheryorigin, one natural-origin) were recovered below the adult trap (Table 7).

Table 7. Numbers and general locations of salmon redds and carcasses (includes pre-spawn mortalities) recovered on the Tucannon River spawning grounds, 2019 (the Tucannon Hatchery adult trap is located at rkm 59).

(Brines Rd.).

## Historical Trends in Natural Spawning

Examining historical traits in natural spawning (1985-present), redd density has varied greatly with run size over the years with a high of 8.3 redds/km in 2010 to a low of 0.1 redds $/ \mathrm{km}$ during 1995 (Figure 4; Table 8). Since the program's inception in 1985, the proportion of the total number of redds occurring below the adult trap has increased (1994-1999 data was removed from the graph due to management actions at the trap, and after 2014 since adult outplants began in 2015.) (Figure 5; Table 8). This is likely the result of a combination of fish that are unwilling to enter the TFH fish ladder/trap (see Adult Weir/Trap Evaluations section) and an emphasis on broodstock collection in an effort to reduce the risk of extinction.

Figure 4. Spring Chinook redd density (redds/km) in the Tucannon River, 1986-2019.

Figure 5. The proportion of redds above Marengo that were either above the adult trap/weir or below the adult trap/weir with trend lines, 1985-1993 and 2000-2014.

Note: - indicates the river was not surveyed in that section during that year.
${ }^{\text {a }}$ Excludes redds found below the Marengo stratum.
${ }^{\mathrm{b}}$ Includes all redds counted during redd surveys.
${ }^{\text {c }}$ The 1985 redd counts were revised to account for all redds during the spawning season (WDFW 2017).

## Stream Nutrient Enrichment

The majority of hatchery broodstock carcasses have traditionally been buried on-site at LFH after spawning. However, declines in salmonid abundance during the last century have resulted in decreased deposition of marine-derived nutrients and pose a significant restraint in the recovery of threatened and endangered Pacific salmon (Nehlsen et al. 1991; Scheuerell et al. 2005). The importance of marine derived nutrients to salmon recovery efforts has prompted local volunteer groups and state, federal, and tribal agencies to add supplemental nutrients into freshwater habitats, especially in salmon depleted habitats (Kohler et al. 2012). Stream nutrient enrichment efforts in the Tucannon River had been sporadic during the history of the hatchery program. Stream nutrient enrichment has been occurring on an annual basis since 2016, however, the large freezer broke down in the summer of 2019. As such, no spring or fall Chinook carcasses from spawning could be kept/frozen which prevented stream nutrient enrichment during 2019. It is hoped that stream nutrient enrichment will begin again in 2020 if funding is available to repair the freezer.

## Genetic Sampling

During 2019, we collected 147 DNA samples (tissue samples) from hatchery broodstock and carcasses collected from the spawning grounds (34 natural origin and 113 hatchery origin). These samples were sent to the WDFW genetics lab in Olympia, Washington for storage. Genetic samples from the broodstock were also collected and sent to the Idaho Department of Fish and Game for parentage-based tagging analysis. Genotypes, allele frequencies, and tissue samples from previous sampling years are available from WDFW's Genetics Laboratory.

## Age Composition, Length Comparisons, and Fecundity

We determine the age composition of each year's returning adults from scale samples of natural origin fish, and both scales and CWTs from hatchery-origin fish collected for broodstock and from carcasses collected during spawning ground surveys. This enables us to compare ages of natural and hatchery-reared fish, and to examine trends and variability in age structure. The recovery of jack salmon from the river is low and jacks are typically not collected for broodstock, so their representation is biased low compared to observations from the adult trap.

Overall, hatchery origin fish return at a younger age than natural origin fish and have fewer age5 fish in the population (Figure 6). This difference is likely due to larger size-at-release that can lead to higher proportions of early maturating fish (hatchery origin smolts are generally 40-50
mm greater in length than natural smolts). The age composition for both hatchery and natural origin fish that returned in 2019 had fewer age- 3 and 5 fish compared to the historical age composition (Figure 6). This is likely the result of poor ocean conditions during the past few years. There has been a slight decrease in the mean age (weighted) of males and females for both hatchery and natural origin fish (Figure 7) during recent brood years, which may also be related to poor ocean conditions (Peterson et al. 2014, Kintisch 2015). We will continue to monitor this trend. The age composition by brood year for natural and hatchery origin fish is found in Appendix C.

Figure 6. Historical (1985-2018), and 2019 age composition (run year) for spring Chinook in the Tucannon River.

Figure 7. Weighted mean age of natural and hatchery origin males (NM, HM) and natural and hatchery origin females (NF, HF) for the 1985 to 2014 brood years for spring Chinook in the Tucannon River.

Another metric monitored on returning adult natural and hatchery origin fish is size at age, measured as the mean post-orbital to hypural-plate $(\mathrm{POH})$ length. We examined size at age for age-4 adult returns using multiple comparison analysis from 1985-2019 and found a significant difference ( $P<0.001$ ) in mean POH length between age-4 natural and hatchery-origin female, and age-4 natural and hatchery-origin male spring Chinook salmon (Figure 8).

Figure 8. Mean post-orbital to hypural-plate ( POH ) length comparisons between age-4 natural and hatcheryorigin males (NM and HM) and natural and hatchery-origin females (NF and HF) with $\mathbf{9 5 \%}$ confidence intervals for the years 1985-2019.

To estimate fecundities (number of eggs/female) from the 2019 return year, dead eggs were counted for each female and a subsample of 100 live eyed-eggs was weighed. The total mass of live eggs was also weighed and divided by the average weight per egg to yield total number of live eggs. This estimate was decreased by $4 \%$ to compensate for adherence of water on the eggs (WDFW Snake River Lab, unpublished data). Fecundities of natural and hatchery origin fish from the Tucannon River program have been documented since 1990 (Table 9). We performed an analysis of variance to determine if there were differences in mean fecundities of hatchery and natural origin fish. The significance level for all statistical tests was 0.05 . Natural origin females were significantly more fecund than hatchery origin fish for both age-4 ( $P<0.001$ ) and age-5 fish ( $P<0.001$ ). These data correspond with data collected by Gallinat and Chang (2013) that examined the effects of hatchery rearing on selected phenotypic traits of female Tucannon River spring Chinook salmon. They found that hatchery origin females had significantly lower fecundity than natural origin fish after correcting for body size.

Table 9. Average number of eggs/female (n, SD) by age group of Tucannon River natural and hatchery origin broodstock, 1990-2019 (partial spawned females are excluded).

## Arrival and Spawn Timing Trends

We monitor peak arrival and spawn timing to determine whether the hatchery program has caused a shift (Table 10). Peak arrival dates were based on the greatest number of fish trapped on a single day. Peak spawn in the hatchery was determined by the day when the most females were spawned. Peak spawning in the river was determined by the highest weekly redd count.

Peak arrival to the TFH adult trap for both natural and hatchery origin fish during 2019 was identical to the historical average (Table 10). Peak spawning date in the hatchery was 10 September for both hatchery and natural origin fish and was similar to the historical mean (Table 10). The duration of spawning in the hatchery (22 days) was also close to the historical mean. Spawning in the river peaked on 11 September. The duration of active spawning in the Tucannon River ( 38 days) was also within the range found from previous years.

Natural origin fish typically arrive earlier and at a slightly faster rate than hatchery origin fish (Figure 9). On average, about half of the total run of hatchery origin fish typically arrives at the adult trap by 12 June (Figure 9). After the end of June, the hatchery fish tend to arrive at the adult trap at a slightly faster rate than natural origin fish.

Table 10. Peak dates of arrival of natural and hatchery salmon to the TFH adult trap and peak (date) and duration (number of days) for spawning in the hatchery and river, 1986-2019.

${ }^{\text {a }}$ Too few natural salmon were trapped in 1995 and 1999 to determine peak arrival.
${ }^{\mathrm{b}}$ Access restrictions during the Columbia Complex Forest Fire prohibited spawning ground surveys during the beginning of spawning.
c Unspawned females determined to be in excess of eggtake goals were returned to the river for natural spawning which may have truncated duration of spawning in the hatchery.

Figure 9. Cumulative run timing by date at the Tucannon Fish Hatchery adult trap on the Tucannon River for both natural and hatchery origin Tucannon River spring Chinook salmon, 1994-2019.

## Total Run-Size

During 2019, two males (one natural and one hatchery) were the only fish passed above the trap. However, some adults were able to bypass the TFH trap/intake dam and we counted three redds above the trap. No carcasses were recovered above the trap so we could not estimate a bypass rate. We calculated the number of fish above the trap by using the fish/redd estimate (1.97 from the spawning escapement calculation in the next section) for an estimate of six. We also multiplied the fish/redd estimate by the number of redds below the trap (8) for a total of 16 fish below the trap.

The run-size estimate for 2019 was calculated by adding the estimated number of fish upstream of the TFH adult trap (6), the estimated fish below the weir (16), adipose clipped strays killed at the trap (1), pre-spawn mortality of fish held for outplanting (10), the number of broodstock collected (149), and jacks (21) held for outplanting (Table 11). Run-size for 2019 was estimated to be 203 fish ( 43 natural adults, 2 natural jacks, and 129 hatchery adults, 29 hatchery-origin jacks). Historical breakdowns are provided in Appendix D.

a In 1994, 1995, 1998 and 1999, fish were not passed upstream, and in 1996 and 1997, high pre-spawning mortality occurred in fish passed above the trap, therefore; fish/redd ratio was based on the sex ratio of broodstock collected.
b From 1985-1989 the TFH trap was temporary, thereby underestimating total fish passed upstream of the trap. The 1985-1989 fish/redd ratios were calculated from the 1990-1993 average, excluding 1991 because of a large jack run.
${ }^{c}$ This total includes stray fish that are killed at the trap and pre-spawn mortalities of fish held at LFH for adult outplanting. During 2016, jacks were killed outright at the adult trap and are included in this total. During 2017, jacks were killed at LFH.
${ }^{\text {d }}$ Effort in looking for pre-spawn mortalities has varied from year to year with more effort expended during years with poor conditions or large runs.
e The 1985 redd counts were revised on the SASI database to account for all redds during the spawning season (WDFW 2017).
${ }^{f}$ The fish/redd ratio was not used to estimate the number of fish below the adult trap due to survival differences between outplanted fish and fish that were passed upstream.
${ }^{\mathrm{g}}$ This total includes 149 adults kept for spawning and 21 jacks that were held and then outplanted but not recovered.

## Spawning Escapement

To calculate spawning escapement, we assume one redd per female (Murdoch et al. 2009) and multiply the number of redds by the sex ratio (e.g., 1.02 males: 1 female $=2.02$ fish/redd) of the pre-spawning population that was collected at the adult trap (i.e., no carcass collection bias issues). This should provide a more accurate expansion method than simply applying a constant value based on assumptions, or data from other studies, since it incorporates the natural variability that occurs in most populations (Murdoch et al. 2010). Because spawner distribution of hatchery and natural origin fish may be different, we expanded the natural and hatchery fish by reach [Wilderness, HMA (above trap), HMA (below trap), Hartsock, Marengo, and below Marengo] based on carcass recoveries. The total for all reaches equals the spawning escapement.

Sex ratio from the adult trap was only available from 2000 to present. For 1985 to 1999, we used corrected carcass data based on the methodology of Murdoch et al. (2010). For years when the corrected carcass data produced clear outliers, or produced spawning escapements greater than the run escapement, we used data cited by Meekin (1967) that cited an average of 2.20 adults/redd and proportionately adjusted that figure up during years with high jack returns. The spawning escapement for 2019 was 22 fish ( 8 natural-origin, 14 hatchery-origin) based on 1.97 fish per redd. The estimated spawning escapement for 1985 to 2019 is found in Table 12.

Table 12. Estimated spawning escapement and the calculation methodology used for the 1985 to 2019 run years.

| Run <br> Year | Number <br> of Redds | Spawning <br> Escapement | Natural:Hatchery <br> Ratio | Fish/Redd | Methodology |

${ }^{\text {a }}$ The 1985 redd counts were revised on the SASI database to account for all redds during the spawning season (WDFW 2017).

## Coded-Wire Tag Sampling

Broodstock collection, pre-spawn mortalities, and carcasses recovered during spawning ground surveys provide representatives of the annual run that can be sampled for CWT study groups (Table 13). In 2019, based on the estimated escapement of hatchery and natural origin fish to the river, we sampled approximately $80 \%$ of the run (Table 14).

Table 13. Coded-wire tag codes of hatchery salmon sampled at LFH and the Tucannon River, 2019.

## Stray Salmon into the Tucannon River

Spring Chinook from other river systems (strays) are periodically recovered in the Tucannon River, although they were generally at a low proportion of the total run (Bumgarner et al. 2000). However, Umatilla River hatchery strays accounted for 8 and $12 \%$ of the total Tucannon River run in 1999 and 2000, respectively (Gallinat et al. 2001). Increased strays, particularly from the Umatilla River, was a concern since it exceeded the $5 \%$ stray proportion of hatchery fish deemed acceptable by NOAA Fisheries, and was contrary to fish management intent for the Tucannon River. In addition, the Oregon Department of Fish and Wildlife (ODFW) and the Confederated Tribes of the Umatilla Indian Reservation (CTUIR) did not mark a portion of Umatilla River origin spring Chinook with an RV or LV fin clip (65-70\% of releases), or CWT for the 19971999 brood years. Because of that action, some stray fish that returned from those brood years were physically indistinguishable from natural origin Tucannon River spring Chinook. Scale samples were collected from adults in those brood years to determine hatchery-origin fish based on scale pattern analysis. However, we are unable to differentiate between unmarked Tucannon fish and unmarked strays based on scale patterns. Beginning with the 2000 BY, Umatilla River hatchery-origin spring Chinook were $100 \%$ marked (adipose clipped), however, the implementation of a "stepping stone" hatchery management protocol for the Umatilla Hatchery Program has resulted in a portion of Umatilla Hatchery releases being unclipped (but 100\% CWT) beginning with the 2009 BY. Unfortunately, because of that mark/tag, they are identical to Tucannon fish. As such, this hinders our ability to selectively remove stray hatchery fish during broodstock collection, or from fish passed upstream at the TFH adult trap. We will continue to monitor the Tucannon River and emphasize the need for external marks and CWTs for Umatilla River releases.

One stray (AD clip/no wire) was killed outright at the adult trap during 2019 (Appendix E). After expansions, strays accounted for an estimated $0.5 \%$ of the total 2019 run (Appendix E).

An added concern for the future is the implementation of a new hatchery program for the Touchet River using Carson stock spring Chinook that will begin to return as early as 2021 (BY18). Potential straying from this hatchery program into the Tucannon River would be additive to the current stray rates being observed in the Tucannon River and could lead to outbreeding depression. All juveniles from the new Touchet River spring Chinook program will be $100 \%$ AD-clipped, with $34 \%$ of the production receiving CWT and $6 \%$ receiving PIT tags to monitor potential straying into the Tucannon River.
The increased use of passive integrated transponder (PIT) tags by fish and wildlife agencies and the utilization of in-stream PIT tag arrays in the Tucannon River have permitted us to identify the origin of some spring Chinook PIT tagged from other locations during 2019. Thirteen fish originally PIT tagged at locations other than the Tucannon River were detected in the Tucannon

River (Table 15). The majority of these fish (12) were of unknown origin that were tagged as adults at Lower Granite Dam and eventually returned back downstream and entered the Tucannon River (Table 15). These fish could be Tucannon origin fish that overshot the river and returned back, however their actual origin is unknown. One stray (Sawtooth Fish Hatchery, IDFG) originally PIT tagged as a juvenile (2014 BY) was also detected in the Tucannon (Table 15).

Table 15. Tucannon River PIT tag array detections of spring Chinook originally tagged at locations other than the Tucannon River during 2019.

| 2018 | 14,937 | 366 | --- | 2 (0.01\%) | 0 | --- |
| Totals | 176,232 | 24,342 | 6,028 | 383 (0.22\%) | 193 (0.79\%) | 10 (0.17\%) |

From the detected returns, 140 (24\%) of the returning PIT tagged spring Chinook were detected upstream of the Tucannon River (Table 17; Appendix F). Forty-two of these fish (7\%) had their last detections at or above Lower Granite Dam (Table 17; Appendix F). The overshoot rate has generally decreased over time and it is unknown whether this is related to changes in smolt release methods (from direct release to acclimation ponds with volitional release), changes in hydropower operations and river flows, changes in the proportion barged downstream, increases in tagging numbers/sample size, or greater detection capabilities in the Tucannon River (Table 17). This does not appear to be a hatchery effect as both natural and hatchery origin fish overshoot the Tucannon River (Table 17). Non-direct homing behavior has been documented for
adult Chinook in the Columbia River System (Keefer et al. 2008), and similar percentages of natural origin spring Chinook from the John Day River have been documented bypassing that river (Jim Ruzycki, ODFW, personal communication). However, more research into these events should be conducted to examine whether they are natural straying occurrences, or if it is related to hydropower operations. The installation of PIT tag arrays in the Tucannon River during the past few years [Lower Tucannon River (LTR) at rkm 2.2-2005, Middle Tucannon River (MTR) at rkm 17.8 and Upper Tucannon River (UTR) at rkm 44.4-2011, and Tucannon Fish Hatchery (TFH) at rkm 59.2 - 2012] have enabled us to document that the majority of the Tucannon spring Chinook that overshoot are able to make it back (about 70\%) to the Tucannon River (Table 17). Returning spring Chinook overshooting the Tucannon River continues to be a concern, especially if they are unable to return to the Tucannon River, or if they return in a more compromised state (e.g., injuries from additional dam crossings, added energy expenditure), and may partially explain why this population has been slow to respond to recovery and supplementation actions.

Table 17. Number and origin of PIT tagged Tucannon River spring Chinook returns that overshot the Tucannon River (includes fish that were last detected returning downstream towards the Tucannon River) and also detected at Lower Granite Dam (LGR) that stayed above LGR Dam. Years with installed in-stream PIT tag arrays (2005-2018) are included for comparison.

## Juvenile Salmon Evaluation

## Hatchery Rearing, Marking, and Release

The BY18 supplementation juveniles $(196,275)$ were tagged with CWT $(63 / 74 / 21)$ at LFH from 5 March to 12 March 2019. Fish were transferred to Dworshak NFH during 21-24 May. While rearing at Dworshak NFH over the summer, a subset of the 2018 BY were exposed to and contracted infectious hematopoietic necrosis virus. However, the low-level mortality resolved on its own, thus no supportive care was deemed necessary. The fish were transferred back to LFH during 12-15 August. Upon return, fish were put into one of the large rearing lakes for the remainder of the rearing cycle until release. This represents a change compared to previous years when fish would be transported to TFH for overwinter rearing. Fish were PIT tagged (target 15,000) on 17 March 2020 at the LFH release structure about one week prior to release. PIT tags are used for outmigration survival (Comparative Survival Study) and adult return estimates.

Brood year 2018 fish were sampled just prior to release by WDFW evaluations staff (Table 18). A total of 1,822 fish were sampled for precocity (external observation only) and mark/tag quality and 262 were sampled for length and weight statistics. The target release size was 38 g fish (12 fpp). Mortalities were scanned for PIT tags and 14,986 PIT tagged fish were released. The 2018 BY smolts were direct stream released on 23-24 March just below Beaver/Watson Bridge (rkm 61.9) as the road to the acclimation pond was washed out due to flooding in early February 2020. An estimated 192,521 BY18 smolts were released. Estimated numbers and size of fish released are provided in Table 19. Historical release numbers are found in Appendix G.

Table 18. Sample size ( N ), mean length (mm), coefficient of variation (CV), condition factor (K), mean weight (g), and precocity of 2018 BY juveniles sampled at LFH lake outlet.

## Smolt Trapping

Evaluation staff operated a 1.5 m rotary screw trap at rkm 3 on the Tucannon River from 15 October 2018 through 12 July 2019 to estimate numbers of migrating juvenile natural spring Chinook. Numbers of each fish species captured by month during the 2019 outmigration can be found in Appendix H. The main outmigration of natural origin spring Chinook for the 2018/2019 outmigration occurred during the spring, with a limited outmigration during the fall and winter months (Figure 10). Prior years have shown increased outmigration in the fall and winter from larger adult returns (Gallinat and Ross 2014, Gallinat and Ross 2015), although even in those years, the majority of the outmigration occurred in the spring.

## Capture Period

Figure 10. Emigration timing of natural spring Chinook salmon captured during smolt trap operations (rkm 3) on the Tucannon River for the 2018-19 migration year.

Natural spring Chinook emigrating from the Tucannon River (BY 2017) averaged 106 mm (Figure 11), with a CV of $7.5 \%$. This is in comparison to a mean length of 131 mm for hatcheryorigin fish (BY 2017) released from Curl Lake Acclimation Pond (Gallinat and Kiefel 2019).

Figure 11. Length frequency distribution of sampled natural spring Chinook salmon captured in the Tucannon River smolt trap, 2018/2019 season.

Each week we attempted to determine trap efficiency by clipping a portion of the caudal fin on a representative subsample of captured migrants and releasing them approximately one kilometer upstream. The percent of marked fish recaptured was used as an estimate of weekly trapping efficiency. In previous reports we attempted to relate trap efficiency to abiotic factors such as stream flow or staff gauge level based on similar juvenile outmigration studies (Groot and Margolis 1991; Seiler et al. 1999; Cheng and Gallinat 2004). We found no significant relationships.

To estimate potential juvenile migrants passing when the trap was not operated for short intervals ( $\leq 5$ days), such as periods when freshets washed out large amounts of debris from the river, we calculated the mean number of fish trapped for three days before and three days after nontrapping periods. The mean number of fish trapped daily was then divided by the estimated trap efficiency to calculate fish passage. The estimated number of fish passing each day was then applied to each day the trap was not operated.

We estimated outmigration based on the approach of Steinhorst et al. (2004). This involved using a Bailey-modified Lincoln-Peterson estimation with 95\% bootstrap confidence intervals by running the Gauss Run-Time computer program (version 7.0). Bootstrap iterations numbered

1,000. The program allows for the division of the out-migration trapping season into strata with similar capture efficiencies as long as at least seven marked recaptures occurred. Strata with less than seven recaptures were grouped with either the preceding or following strata, depending upon similarity in trapping/flow conditions. Where river conditions were similar, we used our best judgment to group the strata.

A number of assumptions are required to attain unbiased estimates of smolt production. How well the assumptions are met will determine the accuracy and precision of the estimates. Some of these assumptions are:

- Survival from release to the trap was $100 \%$.
- All marked fish are identified and correctly enumerated.
- Fish do not lose their marks.
- All fish in the tag release group emigrate (i.e., do not residualize in the area of release).
- Marked fish are caught at the same rate as unmarked fish.

Accurate outmigration estimates are critical for describing survival trends and to measure population response to management actions such as hatchery supplementation and habitat restoration. It has been suggested that researchers test the assumptions of population estimators being used (Peterson et al. 2004; Rosenberger and Dunham 2005). Other WDFW researchers have identified bias in smolt trap efficiency estimates that were conducted similarly to Tucannon River trap efficiency tests. While the evidence of estimator bias and error seem consistent in the literature, our methods differ from those, and must be tested to estimate the level of error, and confirm compliance of the methods with underlying assumptions. If bias in our methods has been consistent over the term of the data, data could be adjusted as appropriate once bias is measured.

In past years, we attempted to measure bias in our efficiency estimates through the use of PIT tags and the PIT tag array that has been deployed in the lower Tucannon River below the smolt trap. Representative groups of fish were fin clipped and PIT tagged to determine smolt trap efficiency based on either recaptures in the smolt trap or detections by the PIT tag array in the Tucannon River. However, the PIT tag array proved unreliable in its detection of juvenile salmonids. If PIT tag technology in the future allows for greater detections of juvenile salmonids, then we will attempt to measure trapping bias again. We estimate that 17,972 (S.E. 3,181.9; 95\% C.I. 13,302-25,871) migrant natural-origin spring Chinook (2017 BY) passed the smolt trap during 2018-2019.

## Smolt Migration to Lower Monumental and McNary Dams

With the use of PIT tags, we monitored the migration travel time and speed of juvenile spring Chinook from the Tucannon River (both hatchery and natural origin) to Lower Monumental and McNary Dams for the 2019 outmigration (Table 20). Hatchery fish were PIT tagged prior to transfer to Curl Lake AP (rkm 66) for acclimation, while natural origin fish were PIT tagged at the Tucannon River smolt trap (rkm 3), described earlier.

Hatchery fish were volitionally released from Curl Lake AP from 4 April to 3 May 2019. Given the length of the volitional release period, we chose the midway point of 18 April as the "release date" for this analysis. Natural origin spring Chinook were released immediately following PIT tagging at the smolt trap, so the release date/time provided in the PTAGIS tagging files have been used for travel time/speed calculations. Natural origin fish used in this analysis were PIT tagged at the smolt trap and released between 19 February to 31 May 2019 (Table 20). Naturalorigin fish tend to have faster migration time to the dams than hatchery-origin fish (Table 20).

From 2007 to 2017, barge transportation at Lower Monumental Dam typically began between 112 May (PTAGIS website 2020). In 2018 and 2019, transportation began on 24 and 23 April, respectively. For 2018 and 2019, spring Chinook were released later (last week of April, first week of May) per the request of the co-managers to allow for greater potential transportation at Lower Monumental Dam. The releases in 2019 resulted in a shift in the emigration timing compared to previous years (Figure 12).

Table 20. Median and mean travel time and outmigration speed of hatchery and natural-origin Tucannon River spring Chinook to Lower Monumental and McNary Dams in 2019.

## Survival Rates

Point estimates of population sizes have been calculated for various life stages (Tables 21 and 22) of natural and hatchery-origin spring Chinook from spawning ground and juvenile midsummer population surveys, smolt trapping, and fecundity estimates. Survivals between life stages have been calculated for both natural and hatchery salmon to assist in the evaluation of the hatchery program. These survival estimates provide insight as to where efforts should be directed to improve not only the survival of fish produced within the hatchery, but fish in the river as well.

As expected, juvenile (egg-parr-smolt) survival rates for hatchery fish are considerably higher than for naturally reared salmon (Table 23) because they have been protected in the hatchery. However, SARs to the Tucannon River of natural salmon were almost eight times higher (based on geometric means) than for hatchery-reared salmon (Tables 24 and 25). With the exception of the 2006 brood year, hatchery SARs (mean $0.24 \%$; geometric mean $0.17 \%$ ) documented from the 1985-2014 broods have been well below the original LSRCP survival assumption of $0.87 \%$ (which was used to size the original hatchery program of 132,000 smolts). Hatchery SARs for Tucannon River salmon need to substantially improve to meet the mitigation goal of 1,152 hatchery adult salmon. The target size at release was increased to 38 g fish ( 12 fpp ) beginning with the 2011 brood year in an attempt to improve poor smolt-to-adult return survival rates.

a 1985 and 1989 mean fecundity of natural females is the average of 1986-88 and 1990-93 brood years; 1999 mean fecundity of natural fish is based on the mean of 1986-1998 brood years.
b Numbers do not include down river harvest or other out-of-basin recoveries.
c Number of smolts is less than actual release number. 57,316 parr were released in October 1993, with an estimated $7 \%$ survival. Total number of hatchery fish released from the 1992 brood year was 140,725 . We therefore use the listed number of 87,752 as the number of smolts released.
d Parr determined to be in excess of program goals were released at Russell Springs and are not included in number of parr and smolts.

a Expanded numbers are calculated from the proportion of each known age salmon recovered in the river and from broodstock collections in relation to the total estimated return to the Tucannon River. Expansions do not include down river harvest or Tucannon River fish straying to other systems.
b One known (expanded to two) Age 6 salmon was recovered.
c Numbers of smolts obtained from estimates in the annual reports.
d The 2015 and 2016 SARs are not included in the mean.

a Expanded numbers are calculated from the proportion of each known age salmon recovered in the river and from broodstock collections in relation to the total estimated return to the Tucannon River. Expansions do not include down river harvest or Tucannon River fish straying to other systems.
b The 2015 and 2016 SARs are not included in the mean.

As previously stated, overall survival of hatchery salmon to return as adults was higher than for naturally reared fish because of the early-life survival advantage (Table 23). With the exception of eleven brood years (35\%), naturally produced fish have been below the replacement level (Figure 13; Table 26). Based on adult returns from the 1985-2015 broods, naturally reared
salmon produced only 0.67 adults for every spawner, while hatchery reared fish produced 2.05 adults (based on geometric means).

Figure 13. Return per spawner (with replacement line) for the 1985-2015 brood years (2015 incomplete brood year).

Table 26. Progeny-to-parent survival estimates of Tucannon River spring Chinook salmon from 1985 through 2015 brood years (2015 brood year incomplete).

Beginning with the 2006 brood year, the annual smolt goal was increased from 132,000 to 225,000 to help offset for the higher mortality of hatchery-origin fish after they leave the hatchery. This should increase adult salmon returns back to the Tucannon River. However,
based on current hatchery SARs the increase in production would still not produce enough adult returns to reach the LSRCP mitigation goal. Hatchery production changes that result in increased survival/return numbers may result in a Proportionate Natural Influence (PNI) of less than 0.5 . This level is generally not considered acceptable for supplementation programs. Historically the PNI for the Tucannon Spring Chinook Program has generally been above 0.5 (Appendix I).

The long-term restoration goal for the State of Washington is to provide a total annual return of between 2,400-3,400 hatchery and natural origin spring Chinook salmon back to the Tucannon River (SRSRB 2006) that should include at least 750 natural origin fish over a 10-year geometric mean (population viability threshold) (ICTRT 2008). Natural origin returns had been increasing, but decreased during recent years (2016-2019), likely due to poor ocean conditions (Figure 14).

Figure 14. Tucannon River spring Chinook natural origin returns with the moving ten-year geometric mean (black line) for the 1985-2019 run years.

## Fishery Contribution and Out-of-Basin Straying

The original goal of the LSRCP supplementation program was to enhance returns of salmon to the Tucannon River by providing 1,152 adult hatchery origin fish (the number estimated to have been lost to the project area due to the construction and operation of the Lower Snake River hydropower system) to the river from hatchery-reared smolt releases. Such an increase would allow for limited harvest and increased spawning. However, hatchery adult returns have always been below the mitigation goal (Figure 15). Based on CWT recoveries reported to the Regional Mark Information System (RMIS) database (Appendix J), sport and commercial harvest combined accounted for an average of less than $6 \%$ of the adult hatchery fish recovered for the 1985-1996 brood years. Increased fishery impacts occurred for the 1997 through 1999 broods when the states implemented mark-selective fisheries in the lower Columbia River (fishery harvest comprised an average of $19 \%$ for hatchery fish recoveries). As such, the WDFW subsequently stopped adipose fin clipping spring Chinook hatchery production from the Tucannon River (Gallinat et al. 2001) to lessen non-tribal fishery impacts from the Columbia River, and newly implemented Snake River fisheries. This change in marking has resulted in lower sport fishery impacts. Based on CWT recoveries for the 2000-2015 brood years, harvest (primarily commercial) has accounted for only $5.8 \%$ of the hatchery adult CWT recoveries (Appendix J).

Out-of-basin stray rates of Tucannon River spring Chinook have generally been low (Appendix J ), with an average of $1.1 \%$ of the adult hatchery fish straying to other river systems/hatcheries for brood years 1985-2015 (range 0-20\%). Recent (2005-2015 BYs) locations that Tucannon River spring Chinook have strayed are listed in Table 27.

Figure 15. Total escapement for Tucannon River spring Chinook salmon for the 1985-2019 run years.

Table 27. Summary of Tucannon River spring Chinook recovered outside of the Tucannon River and represent possible strays to other areas (2005-2015 brood years).

## Adjusted Hatchery SAS

Using CWT recoveries from the RMIS database, we adjusted Tucannon River spring Chinook hatchery smolt-to-adult survival (SAS) to include all known recoveries both from within and outside the Tucannon River. Increased fishing mortality resulted in higher adjusted SAS for the 1997, 1998, and 2006 brood years. With minor exceptions (1997 and 2006 brood years), even after adjustment, hatchery SAS rates were still below the original LSRCP survival assumption of 0.87\% (Table 28).

Table 28. Hatchery SAS adjusted for recoveries from outside the Tucannon River subbasin as reported in the RMIS database, 1985-2014 brood years. (Data downloaded from RMIS database on 12/16/19).

| Brood Year | Estimated Number of Smolts | Expanded Return to Tucannon | Expanded Other Returns ${ }^{\text {a }}$ | Grand Total of CWT Hatchery Origin Recoveries | Original Hatchery SAR (\%) | Adjusted <br> Hatchery SAS (\%) |

${ }^{\text {a }}$ Includes expanded RMIS CWT recoveries from sources outside the Tucannon River Subbasin (i.e., sport and commercial fisheries, Tucannon strays in other river systems, etc.).

## Conclusions and Recommendations

Washington's LSRCP hatchery spring Chinook salmon program in the Tucannon River has failed to return adequate numbers of adults to meet the mitigation goal for Washington (1,152). This has occurred because SARs of hatchery origin fish have been consistently lower than what was originally assumed under the LSRCP program development. However, because of the advantage in survival during early life history stages for fish in the hatchery, the progeny-to-parent ratio for hatchery-produced fish has generally been above replacement and therefore may have sustained the overall Tucannon spring Chinook population during years when the population was at critically low levels. For a while, we had seen a significant rebound of natural origin fish and we came close to reaching the within river hatchery (LSRCP) goal of 1,152 fish in 2009 and 2010. Recent returns have been much lower, which is believed to be the result of recent poor ocean conditions. System survivals (in-river, migration corridor, and ocean) must increase in the near future for the hatchery program to succeed, the natural run to persist over the short-term, and the natural population to increase to a level where it can be sustainable over the long-term.

Until that time, the evaluation program will continue to document and study life history survivals, straying, carrying capacity, genotypic and phenotypic traits, and examine procedures within the hatchery that can be changed to improve the hatchery program and the natural population. Based on our previous studies and current data we recommend the following:

1. We continue to see annual differences in phenotypic characteristics of returning salmon (i.e., hatchery fish are generally younger and less fecund than natural origin fish), yet other traits such as run and spawn time are little changed over the program's history. Further, genetic analysis to date has detected little change in the natural population that may have resulted from hatchery actions.

Recommendation: Continue to collect as many carcasses as possible for the most accurate age composition data. Collect biological data (length, run timing, spawn timing, fecundity estimates, DNA samples, smolt trapping, and life stage survival) to document the effects (positive or negative) that the hatchery program may have on the natural population.
2. Based on annual redd densities and historical spring Chinook radio tag data, and PIT tag data from the TFH PIT tag array, the Tucannon Fish Hatchery weir/trap has been an impediment to upstream passage of spring Chinook to the better spawning and rearing habitat upstream of the trap. Numerous options to improve attraction into the ladder/trap have been discussed with some recently implemented.

Recommendation: Monitor changes made to the ladder/trap to see if they improve passage and reduce migration delay for all fish species. If improvements are not seen, seek funding and engineering expertise to modify the design and/or operation of the weir/trap structure.
3. Subbasin and recovery planning for ESA listed species in the Tucannon River have identified factors limiting the spring Chinook population and strategies to recover the population.

Recommendation: Assist population conservation efforts by updating recent carrying capacity/density and straying effects, and productivity estimates of the Tucannon River so that hatchery stocking is appropriate, and hatchery and natural performance is measured against future basin capacity after habitat improvements.
4. We have documented that hatchery juvenile (egg-parr-smolt) survival rates are considerably higher than naturally reared salmon, and hatchery smolt-to-adult return rates are much lower than their natural origin counterpart. We need to identify and address the factors that limit hatchery SARs in order to meet the mitigation goals and for natural production to meet recovery goals.

Recommendation: Continue to compare hatchery and natural survival rates from other reference watersheds compare survival rates documented for Tucannon River spring Chinook. Continue to discuss alternative release strategies with the managers to see if survival rates can be improved to provide greater adult returns. Utilize fish carcasses from hatchery operations for stream nutrient enrichment to improve overall productivity and survival of Tucannon River spring Chinook. Continue to monitor straying into the Tucannon River to insure the addition of Touchet River Carson stock hatchery fish does not go above the NOAA Fisheries acceptable stray proportion of 5\%.
5. Over the last few years, we have documented higher in-river pre-spawn mortality than what was observed historically. The mechanism for this higher loss is thought to be due to a combination of drought years with higher water temperatures and pathogen load. However, the high loss has prompted drastic action within the program, whereby all, or the majority of the returns to the TFH trap between 2015 to 2019 have been collected and held for adult outplanting. Results from the first year (2015) of adult outplants appeared successful, with > $90 \%$ of the fish spawning, contrasted to $30 \%$ survival of fish left in the river. From 20162018, a range of 55-72\% of outplanted fish successfully spawned.

Recommendation: Continue to monitor in-river pre-spawn mortality. Continue intensive monitoring of adult outplants, when that strategy is employed, to determine spawning success. Weigh all pertinent information (pre-spawn mortality rates, outplant success,
predicted run sizes, risk of holding all fish at one facility, etc.) and inform co-managers and NOAA Fisheries on future adult outplants. An agreed upon population threshold trigger is needed to determine whether to pass fish at the adult trap or hold fish at LFH for outplanting. A trigger has been suggested by M\&E staff (allow outplanting below an estimated return of 400 adults) but has yet to be agreed upon by the co-managers.

a Release types are: Tucannon Hatchery Acclimation Pond (H-Acc); Portable Acclimation Pond (P-Acc); Curl Lake Acclimation Pond (C-Acc); and Direct Stream Release (Direct).
b All tag codes start with agency code 63.
c Codes listed in column are as follows: BWT - Blank Wire Tag; CB - Captive Brood; VI-Visual Implant (elastomer); LR - Left Red, RR Right Red, LG-Left Green, RG - Right Green, LY - Left Yellow, RY - Right Yellow, LB - Left Blue, RB - Right Blue, LP - Left Purple; Oxytet. - Oxytetracycline Mark; Crosses: WxW - wild x wild progeny, HxH - hatchery x hatchery progeny, Mixed - wild x hatchery progeny.
${ }^{\text {d }}$ No tag loss data due to presence of both CWT and BWT in fish.
e VI tag only.
${ }^{f}$ No wire.

Washington D.C. 20240

[^0]:    ${ }^{1}$ The project area escapement is 1,152 . It was also assumed that four times that number ( 4,608 fish) would be harvested below the project area. Here "project area" is defined as above Ice Harbor Dam.
    ${ }^{2}$ Formerly Washington Department of Fisheries.

[^1]:    ${ }^{3}$ The use of trade names does not imply endorsement by the Washington Department of Fish and Wildlife.

[^2]:    ${ }^{\text {a }} 1985$ and 1989 mean fecundity of natural females is the average of 1986-88 and 1990-93 brood years.
    ${ }^{\mathrm{b}}$ Number of parr estimated from electrofishing (1985-1989), Line transect snorkel surveys (1990-1992), and Total Count snorkel surveys (1993-2005).
    c Numbers do not include down river harvest or other out-of-basin recoveries.
    d The 1985 redd counts were revised on the SASI database to account for all redds during the spawning season (WDFW 2017).
    ${ }^{\text {e }}$ Smolt estimates could not be estimated with the GAUSS program for the 1991 and 1995 brood years. Numbers of smolts for those brood years were obtained from estimates in the annual reports.

[^3]:    ${ }^{\text {a }}$ In years when returns to Tucannon Hatchery are low, adult Chinook arriving at Lyons Ferry Hatchery ladder that are identifiable as Tucannon River hatchery adults may be taken for broodstock.
    ${ }^{\mathrm{b}}$ The actual number taken annually will be subject to the sliding scale in the HGMP, in addition to fish that are collected, held, and used for adult outplants in the Tucannon, but may die while holding, or be used as part of the broodstock, and shall not exceed the totals of each origin identified there.

[^4]:    Abbreviations are as follows: BON - Bonneville Dam, TDA - The Dalles Dam, MCN - McNary Dam, ICH - Ice Harbor Dam, LMO - Lower Monumental Dam, LTR - Lower Tucannon River, MTR - Middle Tucannon River, UTR - Upper Tucannon River, TFH - Tucannon Fish Hatchery, LGO - Little Goose Dam, LGR Lower Granite Dam, AFC - Asotin Creek.
    ${ }^{\text {a }}$ PIT tag adult detection systems were in operation beginning in 1988 for LGR, 1998 for BON, 2002 for MCN, 2005 for both ICH and LTR, 2011 for MTR and UTR, and 2012 for TFH.
    ${ }^{\mathrm{b}}$ This fish was detected bypassing the Tucannon River (LGO or LGR detection) before heading back downstream.
